## Some details on two-phase variances

Thomas Lumley

August 21, 2008

This document explains the computation of variances for totals in two-phase designs. Variances for other statistics are computed by the delta-method from the variance of the total of the estimating functions.

The variance formulas come from conditioning on the sample selected in the first phase

$$\text{var}[\hat{T}] = E\left[\text{var}\left[\hat{T}|\text{phase 1}\right]\right] + \text{var}\left[E\left[\hat{T}|\text{phase 1}\right]\right]$$

The first term is estimated by the variance of  $\hat{T}$  considering the phase one sample as the fixed population, and so uses the same computations as any single-phase design. The second term is the variance of  $\hat{T}$  if complete data were available for the phase-one sample. This takes a little more work.

The variance computations for a stratified, clustered, multistage design involve recursively computing a within-stratum variance for the total over sampling units at the next stage. That is, we want to compute

$$s^{2} = \frac{1}{n-1} \sum_{i=1}^{n} (X_{i} - \bar{X})$$

where  $X_i$  are  $\pi$ -expanded observations, perhaps summed over sampling units. A natural estimator of  $s^2$  when only some observations are present in the phase-two sample is

$$\hat{s}^2 = \frac{1}{n-1} \sum_{i=1}^n \frac{R_i}{\pi_i} (X_i - \hat{\bar{X}})$$

where  $\pi_i$  is the probability that  $X_i$  is available and  $R_i$  is the indicator that  $X_i$  is available. We also need an estimator for  $\bar{X}$ , and a natural one is

$$\hat{\bar{X}} = \frac{1}{n} \sum_{i=1}^{n} \frac{R_i}{\pi_i} X_i$$

This is not an unbiased estimator of  $s^2$  unless  $\hat{\bar{X}} = \bar{X}$ , but the bias is of order  $O(n_2^{-1})$  where  $n_2 = \sum_i R_i$  is the number of phase-two observations.

If the phase-one design involves only a single stage of sampling then  $X_i$  is  $Y_i/p_i$ , where  $Y_i$  is the observed value and  $p_i$  is the phase-one sampling probability. For multistage phase-one designs (not yet implemented)  $X_i$  will be more complicated, but still feasible to automate.

This example shows the unbiased phase-one estimate (from Takahiro Tsuchiya) and the estimate I use, in a situation where the phase two sample is quite small.

First we read the data

```
rei<-read.table(textConnection(</pre>
